1. Programming Languages (5 points)

The project uses C# for all gameplay scripting, which includes game logic, player controls, physics, and UI. It is the main language supported by Unity.

2. Platforms, APIs, Databases, and other technologies used (5 points)

Development is done using the Unity editor (version 6000.3.9f1) for game creation and testing. Version control is managed with GitHub Desktop to allow for collaboration.

3. Execution-based Functional Testing (10 points)

Testing is done iteratively. Each feature/addition is tested individually upon implementation. Once testing is done on an individual feature, integration testing is done with related features.

4. Execution-based Non-Functional Testing (10 points)

Formal non-functional testing has been limited, but basic performance, stability, and responsiveness are kept in mind. The game is run to ensure it is responsive, maintains a stable frame rate and does not crash.

5. Non-Execution-based Testing (10 points)

Informal non-execution-based testing has been minimal. Team members have occasionally looked over each other's work and provide suggestions for improvements, though this has not been structured.
